WRW	wildlife refuge worker

1.0 INTRODUCTION

This Industrial Area (IA) and Buffer Zone (BZ) Sampling and Analysis Plan (SAP) (IABZSAP) Addendum #BZ-05-02 includes specifications to conduct additional soil sampling at the 903 Pad (Individual Hazardous Substance Site [IHSS] 112) during Fiscal Year (FY) 05. This IABZSAP Addendum is a supplement to the IABZSAP (DOE 2004a) and includes existing data, proposed sampling locations, sampling depths, and contaminants of concern, specifically volatile organic compounds (VOCs). This sampling is intended to determine if sources of groundwater VOC contamination are present in soil under the 903 Pad. The location of the 903 Pad is shown on Figure 1.

The 903 Pad area was used to store drums that contained radioactively contaminated oils and VOCs from 1958 to 1967. The liquid in the drums was primarily lathe coolant and/or carbon tetrachloride. However, hydraulic oils, vacuum pump oils, trichloroethene, tetrachloroethene, silicone oils, acetone still bottoms, and other liquids were also stored in these drums. When leaking drums were noted in 1964, the contents of the leaking drums were transferred to new drums. Soil cleanup operations began in 1967. It was suspected that approximately 420 drums leaked to some degree. The total amount of leaked material was estimated at around 5,000 gallons (DOE 2000).

2.0 EXISTING INFORMATION

The remedial action for the 903 Pad was completed in October 2003 with the removal of contaminated soils to a depth of at least 1 foot (ft) across the area. While the objective of the remedial action was to remove radiologically contaminated soils, it was noted that most of the excavated material was also contaminated with VOCs. The areas (cells within the 903 Pad) where high concentrations of VOCs were excavated are shown on Figure 2 in red.

Pre-remedial action borehole and soil gas data also indicate the presence of subsurface VOC-contaminated soils (DOE 2000). Based on the borehole data, VOC-contaminated soils are found in two zones: near surface soils (less than 6 ft below ground surface), and deeper soils near or at the bedrock surface. One sampling location (BH90998) had VOC concentrations in near-surface soil that exceeded action levels (ALs) for the wildlife refuge worker (WRW). However, the near-surface at this location was excavated, and the data are no longer representative. Figure 2 does not show these data. It only presents existing conditions (representative VOC data) and does not show radionuclide activities.

Areas where subsurface VOC-contaminated soils may be present were identified using historical borehole and soil gas data. In addition, the VOC data collected for the waste containers was linked back to the excavated cell and used to indicate what was previously at that location (Figure 2). While this material has been removed, it indicates areas where higher concentrations of VOCs may remain. These data were overlain with the recent remedial action excavation depths to determine what may still remain as a potential source of groundwater contamination.

Based on this information, five areas were identified for further investigation to determine if there are potential sources of groundwater VOC contamination (DOE 2004b). These areas are shown on Figure 2 and listed in order of priority as follows.

- Area 1 – Area with soil gas anomaly and VOC contamination in upper 3 ft (removed during remedial action). There is known VOC contamination at depth (greater than 25 ft), but at low concentrations (tetrachloroethene at 110 ug/kg, trichloroethene at 27 ug/kg).
- Area 2 – Two cells with elevated VOC contamination in excavated material. This area was not deeply excavated.
- Area 3 – One cell with elevated VOC contamination in excavated material. This area was excavated to a depth greater than 4 ft.
- Area 4 – Area with soil gas anomaly and VOC contamination at depth (23-27 ft). Excavated material at this location contained moderate concentrations of VOCs.
- Area 5 – Area south of the 903 Pad with VOCs in near surface soils.

3.0 SAMPLING

Biased soil sampling will be conducted to augment the existing information and data presented on Figure 2. Proposed biased sampling locations (25) are shown on Figure 3. Proposed sampling and analysis specifications for the 903 Pad area are summarized in Table 1 and listed, by investigation area and sampling location, in Table 2.

Sampling will start from either the ground surface or the bottom of 903 Pad excavated areas. All intervals from the start of sampling to 6 ft will be collected and analyzed. Intervals from 6 ft to bedrock will be cored and visually inspected for staining or other signs of contamination. A photo-ionization detector (PID) or similar instrument will be used over the core to detect additional VOC contamination, if present. VOC samples will be collected for core intervals with stained soils or elevated PID readings. VOC samples will be collected for the sample intervals immediately above and immediately below the bedrock surface. If the bedrock surface falls within one sample interval, then two samples will be collected within that interval. Depth to groundwater will be noted as possible.

The actual number of samples collected will depend on the depth to bedrock and the number of intervals with stains or elevated PID readings. Depth to bedrock in the area ranges from 14 to 24 ft below ground surface (DOE 2000). In addition, the number of samples may change after characterization starts based on field conditions and/or sampling results. For example, additional stepout samples will be added as necessary to define the areas of VOC contamination. Changes to sampling specifications will be considered in consultation with the regulatory agencies.

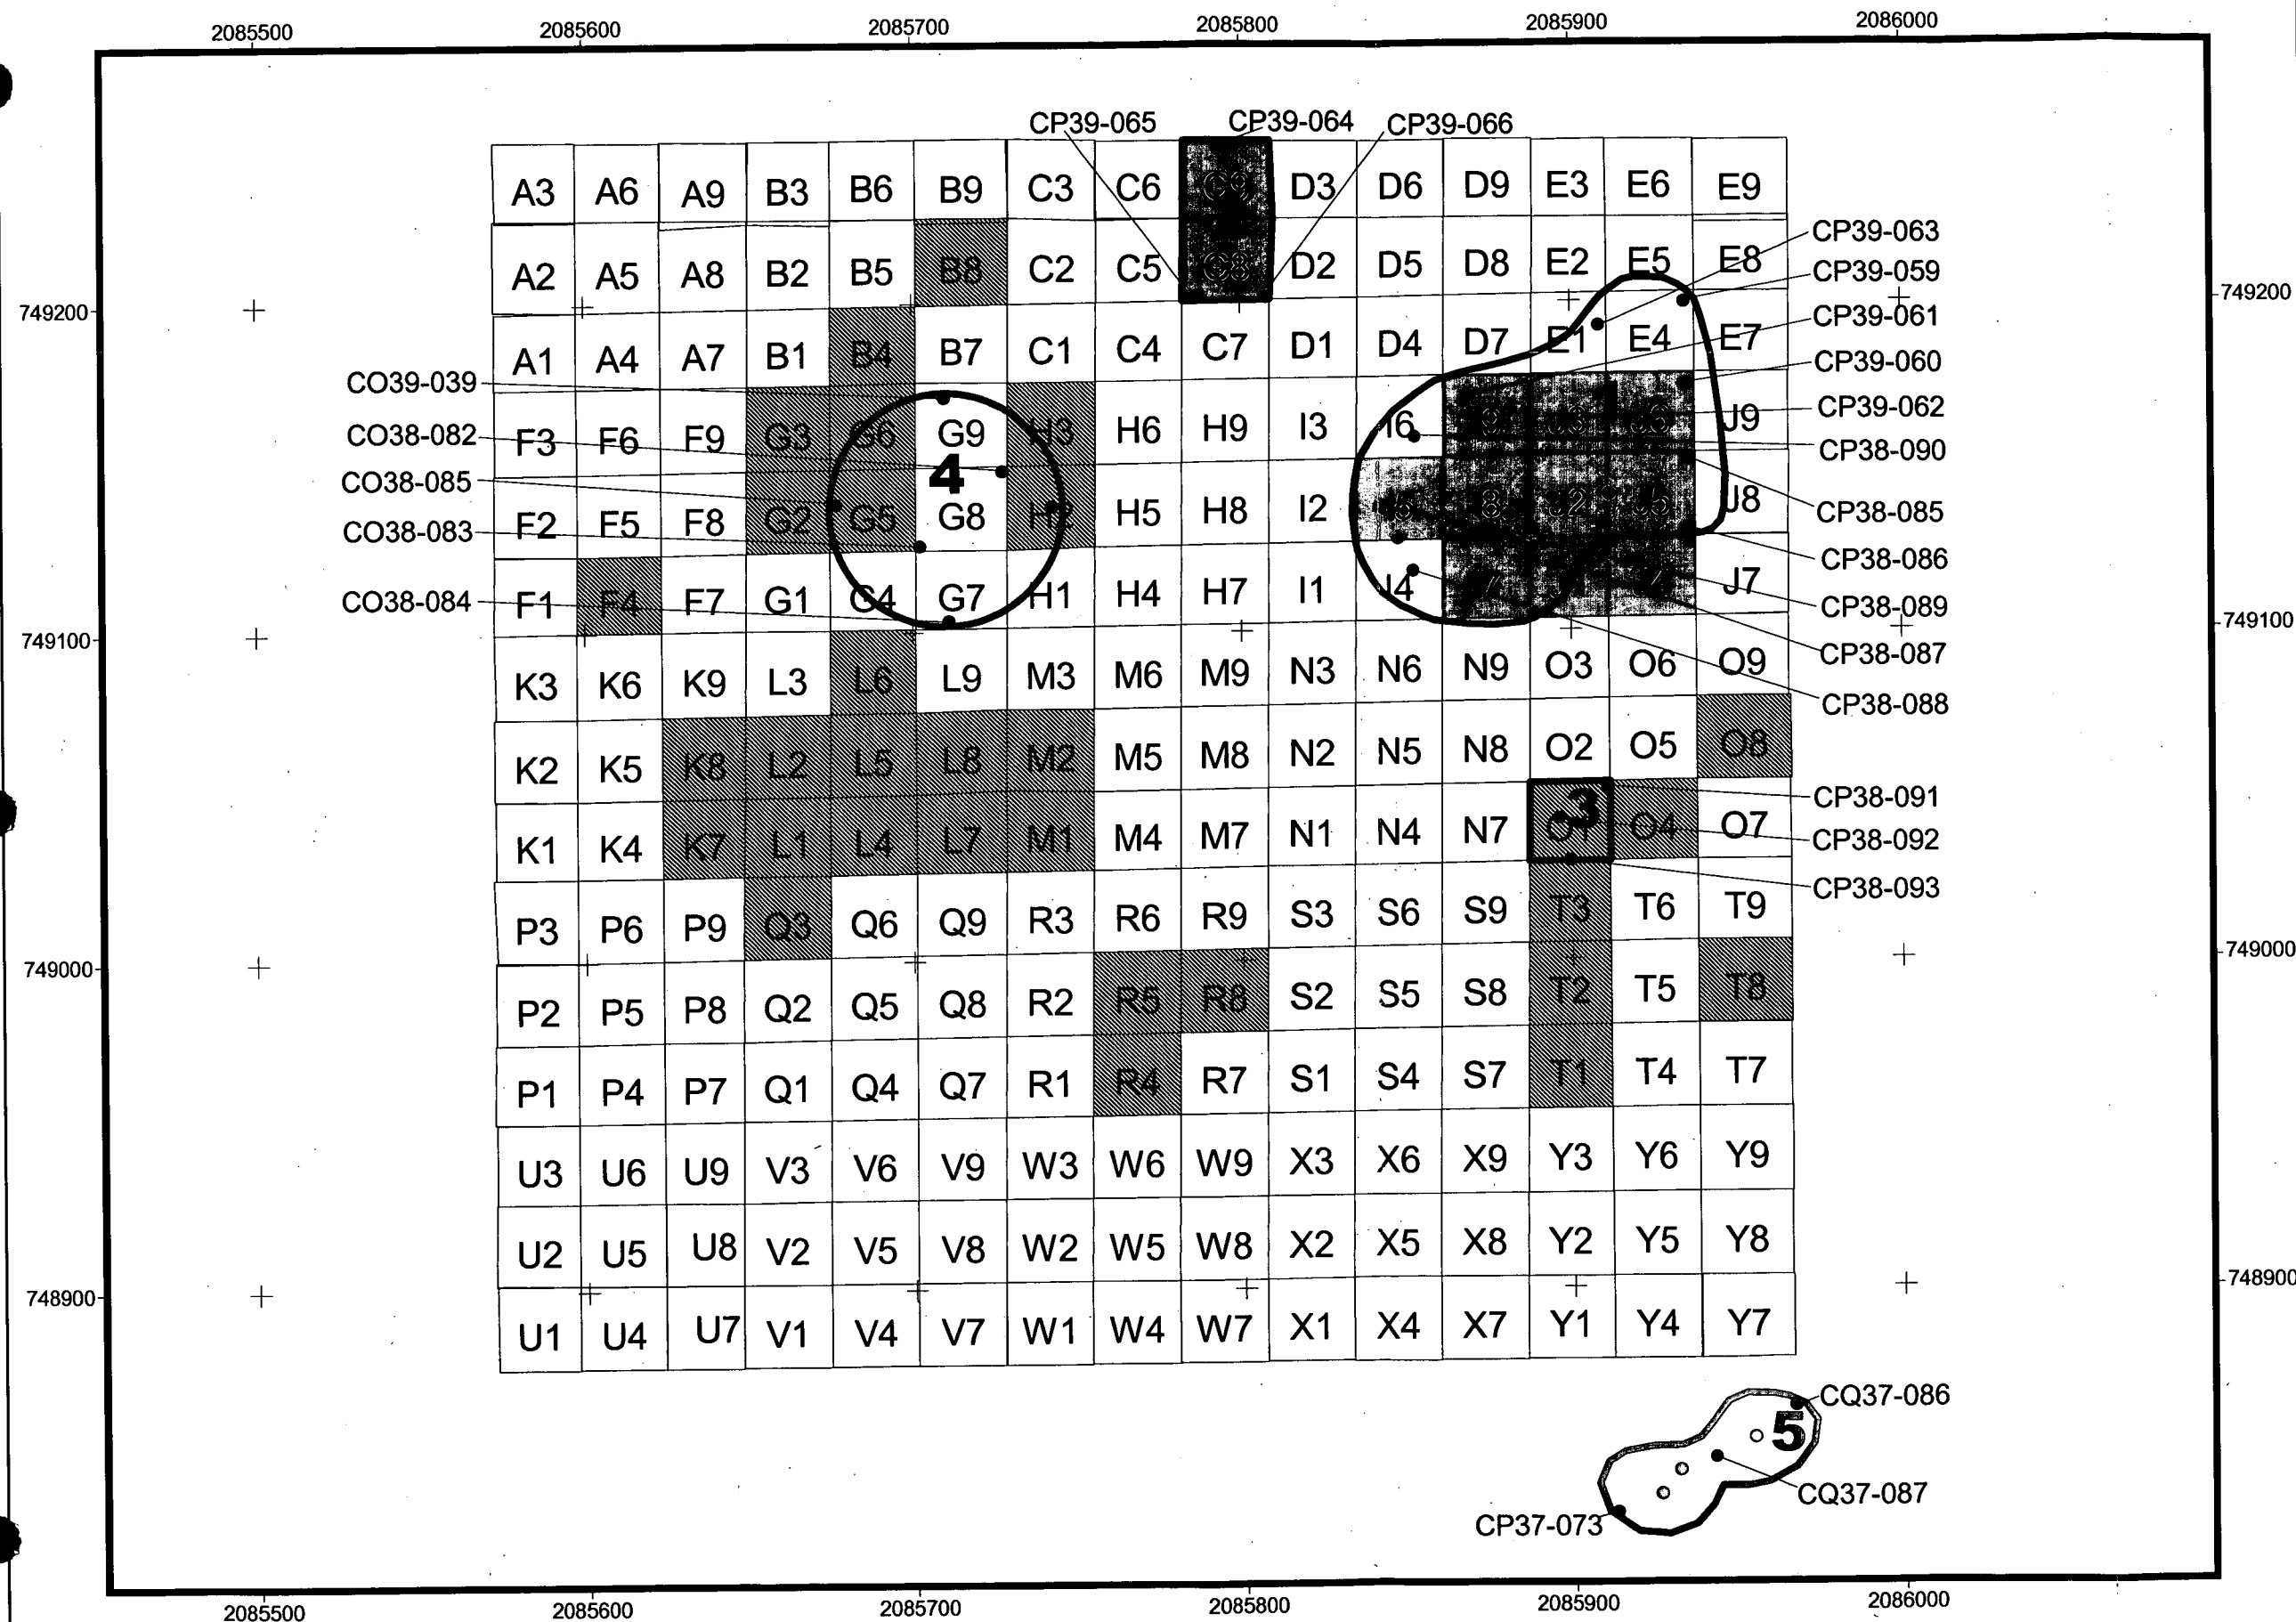

Table 1
Sampling Summary

Category	Total
Number of Sampling Locations	25
Number of Samples Collected	247 (estimated maximum)
Number of VOC Analyses	247 (estimated maximum)
